Newtonian fluids and viscosity

**Definition (Newtonian fluid)**

A **Newtonian fluid** is a viscous fluid for which the shear stress is proportional to the velocity gradient (i.e., to the rate of strain):

\[ \tau = \mu \frac{du}{dy}. \]

Here: \( \tau \) [Pa] is the shear stress (“drag”) exerted by the fluid, \( \mu \) [Pa · s] is the (dynamic or absolute) viscosity, \( \frac{du}{dy} \left[ \frac{1}{s} \right] \) is the velocity gradient perpendicular to the direction of shear.

---

**Non-Newtonian fluids**

For a non-Newtonian fluid the viscosity changes with the applied strain rate (velocity gradient). As a result, non-Newtonian fluids may not have a well-defined viscosity.
Newtonian fluids and viscosity

**Definition (Newtonian fluid)**

A **Newtonian fluid** is a viscous fluid for which the shear stress is proportional to the velocity gradient (i.e., to the rate of strain):

\[ \tau = \mu \frac{du}{dy} . \]

Here: \( \tau \) [Pa] is the shear stress (“drag”) exerted by the fluid,\( \mu \) [Pa \cdot s] is the **dynamic** or **absolute** viscosity,\( \frac{du}{dy} \left[ \frac{1}{s} \right] \) is the velocity gradient perpendicular to the direction of shear.

**Definition (Kinematic viscosity)**

The **kinematic viscosity** of a fluid is defined as the quotient of its absolute viscosity \( \mu \) and density \( \rho \):

\[ \nu = \frac{\mu}{\rho} \left[ \frac{m^2}{s} \right] . \]
Newtonian fluids and viscosity

**Definition (Newtonian fluid)**

A **Newtonian fluid** is a viscous fluid for which the shear stress is proportional to the velocity gradient (i.e., to the rate of strain):

\[ \tau = \mu \frac{du}{dy}. \]

Here: \( \tau \) [Pa] is the shear stress ("drag") exerted by the fluid, \( \mu \) [Pa \cdot s] is the (dynamic or absolute) viscosity, \( \frac{du}{dy} \) \([1 \text{ s}]\) is the velocity gradient perpendicular to the direction of shear.

**Definition (Kinematic viscosity)**

\[ \nu = \frac{\mu}{\rho} \left[ \frac{m^2}{s} \right] \]

Newtonian fluids and viscosity

**Definition (Newtonian fluid)**

A **Newtonian fluid** is a viscous fluid for which the shear stress is proportional to the velocity gradient (i.e., to the rate of strain):

\[
\tau = \mu \frac{du}{dy}.
\]

Here: \(\tau\) [Pa] is the shear stress (“drag”) exerted by the fluid, \(\mu\) [Pa \cdot s] is the (dynamic or absolute) viscosity, \(\frac{du}{dy}\) \([\text{1/s}]\) is the velocity gradient perpendicular to the direction of shear.

**Non-Newtonian fluids**

For a non-Newtonian fluid the viscosity changes with the applied strain rate (velocity gradient). As a result, non-Newtonian fluids may not have a well-defined viscosity.
Constitutive relation for Newtonian fluids

The stress tensor can be decomposed into spherical and deviatoric parts:

\[ \sigma = \tau - p I \quad \text{or} \quad \sigma_{ij} = \tau_{ij} - p \delta_{ij}, \quad \text{where} \quad p = -\frac{1}{3} \text{tr} \sigma = -\frac{1}{3} \sigma_{ii} \]

is the (mechanical) pressure and \( \tau \) is the the stress deviator (shear stress tensor).
Constitutive relation for Newtonian fluids

The **stress tensor** can be decomposed into **spherical** and **deviatoric parts**:

\[ \sigma = \tau - p I \quad \text{or} \quad \sigma_{ij} = \tau_{ij} - p \delta_{ij}, \quad \text{where} \quad p = -\frac{1}{3} \text{tr} \sigma = -\frac{1}{3} \sigma_{ii} \]

is the (mechanical) **pressure** and \( \tau \) is the the **stress deviator** (**shear stress tensor**).

Using this decomposition Stokes (1845) deduced his constitutive relation for Newtonian fluids from three elementary hypotheses:

1. \( \tau \) should be **linear** function of the **velocity gradient**;
2. this relationship should be **isotropic**, as the physical properties of the fluid are assumed to show **no preferred direction**;
3. \( \tau \) should **vanish** if the flow involves **no deformation** of fluid elements.

Moreover, the **principle of conservation of moment of momentum** implies the **symmetry of stress tensor**: \( \sigma = \sigma^T \), i.e., \( \sigma_{ij} = \sigma_{ji} \).

Therefore, the stress deviator \( \tau \) should also be symmetric: \( \tau = \tau^T \), i.e., \( \tau_{ij} = \tau_{ji} \) (since the spherical part is always symmetric).
Constitutive relation for Newtonian fluids

\[ \sigma = \tau - p I \quad \text{or} \quad \sigma_{ij} = \tau_{ij} - p \delta_{ij}, \quad \text{where} \quad p = -\frac{1}{3} \text{tr} \sigma = -\frac{1}{3} \sigma_{ii} \]

1. \( \tau \) should be linear function of the velocity gradient;
2. this relationship should be isotropic, as the physical properties of the fluid are assumed to show no preferred direction;
3. \( \tau \) should vanish if the flow involves no deformation of fluid elements;
4. \( \tau \) is symmetric, i.e., \( \tau = \tau^T \) or \( \tau_{ij} = \tau_{ji} \).

Constitutive relation for Newtonian fluids

\[ \sigma = \mu \left( \nabla u + (\nabla u)^T \right) - p I \quad \text{or} \quad \sigma_{ij} = \mu \left( u_{i|j} + u_{j|i} \right) - p \delta_{ij}. \]

This is a relation for incompressible fluid (i.e., when \( \nabla \cdot u = 0 \)).
Constitutive relation for compressible viscous flow

Definition (Rate of strain)

\[
\dot{\varepsilon} = \frac{1}{2} \left( \nabla \mathbf{u} + (\nabla \mathbf{u})^T \right)
\]

The deviatoric (shear) and volumetric strain rates are given as \( \left( \dot{\varepsilon} - \frac{1}{3} (\text{tr} \, \dot{\varepsilon}) \mathbf{I} \right) \)
and \( \text{tr} \, \dot{\varepsilon} = \dot{\varepsilon} \cdot \mathbf{I} = \nabla \cdot \mathbf{u} \), respectively.
Constitutive relation for compressible viscous flow

<table>
<thead>
<tr>
<th>Definition (Rate of strain)</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ \dot{\varepsilon} = \frac{1}{2} \left( \nabla u + (\nabla u)^T \right) ]</td>
</tr>
</tbody>
</table>

The deviatoric (shear) and volumetric strain rates are given as \( \left( \dot{\varepsilon} - \frac{1}{3} (\text{tr} \, \dot{\varepsilon}) \mathbf{I} \right) \) and \( \text{tr} \, \dot{\varepsilon} = \dot{\varepsilon} \cdot \mathbf{I} = \nabla \cdot \mathbf{u} \), respectively.

Newtonian fluids are characterized by a linear, isotropic relation between stresses and strain rates. That requires two constants:

- the **viscosity** \( \mu \) – to relate the deviatoric (shear) stresses to the deviatoric (shear) strain rates:

  \[ \tau = 2 \mu \left( \dot{\varepsilon} - \frac{1}{3} (\text{tr} \, \dot{\varepsilon}) \mathbf{I} \right), \]

- the so-called **volumetric viscosity** \( \kappa \) – to relate the mechanical pressure (the mean stress) to the volumetric strain rate:

  \[ p \equiv - \frac{1}{3} \text{tr} \, \boldsymbol{\sigma} = -\kappa \text{tr} \, \dot{\varepsilon} + p_0 . \]

Here, \( p_0 \) is the initial hydrostatic pressure independent of the strain rate.
Newtonian fluids are characterized by a linear, isotropic relation between stresses and strain rates. That requires two constants:

- the viscosity $\mu$ – to relate the deviatoric (shear) stresses to the deviatoric (shear) strain rates:
  \[
  \tau = 2\mu \left( \dot{\varepsilon} - \frac{1}{3} (\text{tr} \, \dot{\varepsilon}) I \right),
  \]

- the so-called volumetric viscosity $\kappa$ – to relate the mechanical pressure (the mean stress) to the volumetric strain rate:
  \[
  p \equiv -\frac{1}{3} \text{tr} \, \sigma = -\kappa \text{tr} \, \dot{\varepsilon} + p_0.
  \]

Here, $p_0$ is the initial hydrostatic pressure independent of the strain rate.

**Volumetric viscosity**

There is little evidence about the existence of volumetric viscosity and Stokes made the hypothesis that $\kappa = 0$. This is frequently used though it has not been definitely confirmed.
Newtonian fluids are characterized by a linear, isotropic relation between stresses and strain rates. That requires two constants:

- the **viscosity** $\mu$ – to relate the deviatoric (shear) stresses to the deviatoric (shear) strain rates:
  \[
  \tau = 2\mu \left( \dot{\varepsilon} - \frac{1}{3} (\text{tr} \dot{\varepsilon}) I \right),
  \]

- the so-called **volumetric viscosity** $\kappa$ – to relate the mechanical pressure (the mean stress) to the volumetric strain rate:
  \[
  p \equiv -\frac{1}{3} \text{tr} \sigma = -\kappa \text{tr} \dot{\varepsilon} + p_0.
  \]

Here, $p_0$ is the initial hydrostatic pressure.

**Constitutive relation for compressible Newtonian fluids**

\[
\sigma = 2\mu \left( \dot{\varepsilon} - \frac{1}{3} (\text{tr} \dot{\varepsilon}) I \right) - p I = 2\mu \dot{\varepsilon} - \left( p + \frac{2}{3} \mu \text{tr} \dot{\varepsilon} \right) I,
\]

and after using the definition for strain rate:

\[
\sigma = \mu \left( \nabla u + (\nabla u)^T \right) - \left( p + \frac{2}{3} \mu \nabla \cdot u \right) I \quad \text{or} \quad \sigma_{ij} = \mu (u_i u_j + u_j u_i) - \left( p + \frac{2}{3} \mu u_k u_k \right) \delta_{ij}.
\]

Continuity equation

**Continuity (or mass conservation) equation**

The balance of mass flow entering and leaving an infinitesimal control volume is equal to the rate of change in density:

\[
\frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0.
\]
**Continuity (or mass conservation) equation**

The balance of mass flow entering and leaving an infinitesimal control volume is equal to the rate of change in density:

\[
\frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0.
\]

For **incompressible flows** the density does not change \((\rho = \rho_0\) where \(\rho_0\) is the constant initial density) so

\[
\frac{D\rho}{Dt} = 0 \quad \rightarrow \quad \nabla \cdot \mathbf{u} = 0.
\]

This last **kinematic constraint** for the velocity field is called the **incompressibility condition**.
The general equation of motion valid for any continuous medium is obtained from the principle of conservation of linear momentum:

\[
\frac{D}{Dt} \int_V \rho u \, dV = \int_V b \, dV + \int_S t \, dS
\]

where \( b \) is the body (or volume) force, and \( t \) is the surface traction.
Cauchy’s equation of motion

\[
\frac{D}{Dt} \int_{V} \rho u \, dV = \int_{V} b \, dV + \int_{S} t \, dS
\]

- Use the **Reynolds’ transport theorem**

\[
\frac{D}{Dt} \int_{V} f \, dV = \int_{V} \left( \frac{Df}{Dt} + f \nabla \cdot u \right) \, dV ,
\]

and the **continuity equation**

\[
\frac{D\rho}{Dt} + \rho \nabla \cdot u = 0 ,
\]

for the inertial term:

\[
\frac{D}{Dt} \int_{V} \rho u \, dV = \int_{V} \left[ \frac{D(\rho u)}{Dt} + \rho u \nabla \cdot u \right] \, dV \\
= \int_{V} \left[ \rho \frac{Du}{Dt} + u \left( \frac{D\rho}{Dt} + \rho \nabla \cdot u \right) \right] \, dV = \int_{V} \rho \frac{Du}{Dt} \, dV .
\]
Cauchy’s equation of motion

\[ \frac{D}{Dt} \int_V \rho u \, dV = \int_V b \, dV + \int_S t \, dS \]

- Use the **Reynolds’ transport theorem** and the **continuity equation** for the inertial term:
  \[ \frac{D}{Dt} \int_V \rho u \, dV = \int_V \left[ \frac{D(\rho u)}{Dt} + \rho u \nabla \cdot u \right] \, dV = \int_V \rho \frac{Du}{Dt} \, dV. \]

- Apply the **Cauchy’s formula**: \( t = \sigma \cdot n \), and the **divergence theorem** for the surface traction term:
  \[ \int_S t \, dS = \int_S \sigma \cdot n \, dS = \int_V \nabla \cdot \sigma \, dV. \]
Cauchy’s equation of motion

\[
\frac{D}{Dt} \int_{V} \varrho \mathbf{u} \ dV = \int_{V} \mathbf{b} \ dV + \int_{S} t \ dS
\]

- Use the Reynolds’ transport theorem and the continuity equation for the inertial term:
  \[
  \frac{D}{Dt} \int_{V} \varrho \mathbf{u} \ dV = \int_{V} \left[ \frac{D(\varrho \mathbf{u})}{Dt} + \varrho \mathbf{u} \nabla \cdot \mathbf{u} \right] \ dV = \int_{V} \varrho \frac{D\mathbf{u}}{Dt} \ dV.
  \]

- Apply the Cauchy’s formula: \( t = \sigma \cdot n \), and the divergence theorem for the surface traction term:
  \[
  \int_{S} t \ dS = \int_{S} \sigma \cdot n \ dS = \int_{V} \nabla \cdot \sigma \ dV.
  \]

- Now, the global (integral) form of equation of motion is obtained:
  \[
  \int_{V} \left( \varrho \frac{D\mathbf{u}}{Dt} - \nabla \cdot \sigma - \mathbf{b} \right) \ dV = 0,
  \]
  which, being true for arbitrary \( V \) and provided that the integrand is continuous, yields the local (differential) form.
Cauchy’s equation of motion

\[ \frac{D}{Dt} \int_V \rho u \, d\mathcal{V} = \int_V b \, d\mathcal{V} + \int_S t \, dS \]

- Use the **Reynolds’ transport theorem** and the **continuity equation** for the inertial term:
  \[ \frac{D}{Dt} \int_V \rho u \, d\mathcal{V} = \int_V \left[ \frac{D(\rho u)}{Dt} + \rho u \nabla \cdot u \right] \, d\mathcal{V} = \int_V \rho \frac{Du}{Dt} \, d\mathcal{V}. \]

- Apply the **Cauchy’s formula**: \( t = \sigma \cdot n \), and the **divergence theorem** for the surface traction term:
  \[ \int_S t \, dS = \int_S \sigma \cdot n \, dS = \int_V \nabla \cdot \sigma \, d\mathcal{V}. \]

- Now, the global (integral) form of equation of motion is obtained which, being true for arbitrary \( \mathcal{V} \) and provided that the integrand is continuous, yields the **local (differential) form** – the Cauchy’s equation of motion.

**Cauchy’s equation of motion**

\[ \rho \frac{Du}{Dt} = \nabla \cdot \sigma + b \quad \text{or} \quad \rho \frac{Du_i}{Dt} = \sigma_{ij,j} + b_i \]
Navier–Stokes equations of motion

On applying the constitutive relations of Newtonian incompressible fluids to the Cauchy’s equation of motion of continuous media, the so-called incompressible Navier–Stokes equations are obtained.

Incompressible Navier–Stokes equations

\[
\rho_0 \frac{Du}{Dt} = \mu \Delta u - \nabla p + \rho_0 g \quad \text{or} \quad \rho_0 \frac{Du_i}{Dt} = \mu u_{i|jj} - p_i + \rho_0 g_i ,
\]

(+ the incompressibility constraint:) \( \nabla \cdot u = 0 \) or \( u_{i|i} = 0 \).

Here, the density is constant \( \rho = \rho_0 \), and the body force \( b \) has been substituted by the the gravitational force \( \rho_0 g \), where \( g \) is the gravitational acceleration. Now, on dividing by \( \rho_0 \), using \( \nu = \frac{\mu}{\rho_0} \), and expanding the total-time derivative the main relations can be written as

\[
\frac{\partial u}{\partial t} + (u \cdot \nabla)u = \nu \Delta u - \frac{1}{\rho_0} \nabla p + g \quad \text{or} \quad \frac{\partial u_i}{\partial t} + u_j u_{i|j} = \nu u_{i|jj} - \frac{1}{\rho_0} p_i + g_i .
\]

They differ from the Euler equations by virtue of the viscous term.
Boundary conditions (for incompressible flow)

- Let \( n \) be the unit normal vector to the boundary, and \( m^{(1)}, m^{(2)} \) be two (non-parallel) unit tangential vectors.
- Let \( \hat{u}, \hat{u}_n, \hat{p} \) be values prescribed on the boundary, namely, the prescribed velocity vector, normal velocity, and pressure, respectively.

**Inflow/Outflow velocity or No-slip condition:**

\[
\begin{align*}
u &= \hat{u} \quad (\hat{u} = 0 \text{ for the no-slip condition}).
\end{align*}
\]

**Slip or Symmetry condition:**

\[
\begin{align*}
u \cdot n &= \hat{u}_n \quad (\hat{u}_n = 0 \text{ for the symmetry condition}), \\
(\sigma n) \cdot m^{(1)} &= 0, \quad (\sigma n) \cdot m^{(2)} = 0, \\
&\quad (\text{or: } (\tau n) \cdot m^{(1)} = 0, \quad (\tau n) \cdot m^{(2)} = 0).
\end{align*}
\]

**Pressure condition:**

\[
\sigma n = -\hat{p} n \quad (\text{or: } p = \hat{p}, \quad \tau n = 0).
\]

**Normal flow:**

\[
\begin{align*}
u \cdot m^{(1)} &= 0, \quad \nu \cdot m^{(2)} = 0, \\
(\sigma n) \cdot n &= -\hat{p} \quad (\text{or: } p = \hat{p}, \quad (\tau n) \cdot n = 0).
\end{align*}
\]
Compressible Navier–Stokes equations of motion

On applying the constitutive relations of Newtonian compressible flow to the Cauchy’s equation of motion, the compressible Navier–Stokes equations of motion are obtained.

\[
\frac{\rho}{D} \frac{Du}{Dt} = \mu \Delta u + \frac{\mu}{3} \nabla (\nabla \cdot u) - \nabla p + \rho g \quad \text{or} \quad \frac{\rho}{D} \frac{Du_i}{Dt} = \mu u_{i|ji} + \frac{\mu}{3} u_{j|ji} - p_{i} + \rho g_{i}
\]

(+) the continuity equation:

\[
\frac{D\rho}{Dt} + \rho \nabla \cdot u = 0 \quad \text{or} \quad \frac{D\rho}{Dt} + \rho u_{i|i} = 0.
\]
Compressible Navier–Stokes equations of motion

On applying the constitutive relations of Newtonian compressible flow to the Cauchy’s equation of motion, the **compressible Navier–Stokes equations of motion** are obtained.

Compressible Navier–Stokes equations of motion

\[
\begin{align*}
\frac{\partial \rho}{\partial t} + \nabla \cdot \rho \mathbf{u} &= 0 \\
\frac{\partial \rho}{\partial t} + \nabla \rho \mathbf{u} &= 0 \quad \text{or} \\
\frac{D \rho}{Dt} + \rho \nabla \cdot \mathbf{u} &= 0 \quad \text{or} \\
\frac{D \rho}{Dt} + \rho \mathbf{u} \cdot \nabla \mathbf{u} &= 0.
\end{align*}
\]

- These equations are **incomplete** – there are only 4 relations for 5 unknown fields: \(\rho, \mathbf{u}, p\).
- They can be completed by a **state relationship between \(\rho\) and \(p\)**.
- However, this would normally introduce also another state variable: the temperature \(T\), and that would involve the requirement for energy balance (yet another equations). Such approach is governed by the **complete Navier–Stokes equations for compressible flow**.
- More simplified yet complete set of equations can be used to describe an **isothermal flow with small compressibility**.
**Assumptions:**

1. The problem is **isothermal**.
2. The **variation of \( \varrho \) with \( p \) is very small**, such that in product terms of \( u \) and \( \varrho \) the latter can be assumed constant: \( \varrho = \varrho_0 \).
Small-compressibility Navier–Stokes equations

**Assumptions:**

1. The problem is **isothermal**.
2. The **variation of** \( \varrho \) **with** \( p \) **is very small**, such that in product terms of \( u \) and \( \varrho \) the latter can be assumed constant: \( \varrho = \varrho_0 \).

**Small compressibility is allowed:** density changes are, as a consequence of elastic deformability, related to pressure changes:

\[
\mathrm{d} \varrho = \frac{\varrho_0}{K} \, \mathrm{d} p \quad \rightarrow \quad \frac{\partial \varrho}{\partial t} = \frac{1}{c^2} \frac{\partial p}{\partial t} \quad \text{where} \quad c = \sqrt{\frac{K}{\varrho_0}}
\]

is the acoustic wave velocity, and \( K \) is the elastic bulk modulus. This relation can be used for the continuity equation yielding the following small-compressibility equation:

\[
\frac{\partial p}{\partial t} = - \frac{c^2 \varrho_0}{K} \nabla \cdot \mathbf{u},
\]

where the density term standing by \( \mathbf{u} \) has been assumed constant: \( \varrho = \varrho_0 \). This also applies now to the Navier-Stokes momentum equations of compressible flow \((\nu = \frac{\mu}{\varrho_0})\).
Assumptions:
1. The problem is isothermal.
2. The variation of \( \varrho \) with \( p \) is very small, such that in product terms of \( u \) and \( \varrho \) the latter can be assumed constant: \( \varrho = \varrho_0 \).

Small compressibility is allowed: density changes are, as a consequence of elastic deformability, related to pressure changes.

Navier–Stokes equations for nearly incompressible flow

\[
\frac{\partial u}{\partial t} + (u \cdot \nabla)u = \nu \Delta u + \frac{\nu}{3} \nabla (\nabla \cdot u) - \frac{1}{\varrho_0} \nabla p + g
\]

or
\[
\frac{\partial u_i}{\partial t} + u_j \, u_{i|j} = \nu \, u_{i|jj} + \frac{\nu}{3} \, u_{j|ji} - \frac{1}{\varrho_0} \, p_{|i} + g_{i}
\]

(+ small-compressibility equation:) \[
\frac{\partial p}{\partial t} = -K \nabla \cdot u \quad \text{or} \quad \frac{\partial p}{\partial t} = -K \, u_{i|i}
\]

- These are 4 equations for 4 unknown fields: \( u, p \).
- After solution the density can be computed as \( \varrho = \varrho_0 \left( 1 + \frac{p-p_0}{K} \right) \).
Complete Navier–Stokes equations

**Mass conservation:** \( \frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \)

This is also called the *continuity equation*. 
Complete Navier–Stokes equations

**Mass conservation:** \( \frac{D \rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \)

**Momentum conservation:** \( \rho \frac{D\mathbf{u}}{Dt} = \nabla \cdot \mathbf{\sigma} + \rho \mathbf{g}, \) (here: \( \mathbf{\sigma} = \mathbf{\sigma}^T \)).

These are 3 equations of motion (a.k.a. balance or equilibrium equations). The symmetry of stress tensor (additional 3 equations) results from the conservation of angular momentum.
Complete Navier–Stokes equations

**Mass conservation:** \[ \frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \]

**Momentum conservation:** \[ \rho \frac{Du}{Dt} = \nabla \cdot \mathbf{\sigma} + \rho \mathbf{g}, \quad \text{(here: } \mathbf{\sigma} = \mathbf{\sigma}^T). \]

**Energy conservation:** \[ \frac{D}{Dt} \left( \rho e + \frac{1}{2} \rho \mathbf{u} \cdot \mathbf{u} \right) = -\nabla \cdot \mathbf{q} + \nabla \cdot (\mathbf{\sigma} \cdot \mathbf{u}) + \rho \mathbf{g} \cdot \mathbf{u} + h. \]

Here: \( e \) is the *intrinsic energy* per unit mass, \( \mathbf{q} \) is the *heat flux vector*, and \( h \) is the *power of heat source* per unit volume. Moreover, notice that the term \( \frac{1}{2} \rho \mathbf{u} \cdot \mathbf{u} \) is the *kinetic energy*, \( \nabla \cdot (\mathbf{\sigma} \cdot \mathbf{u}) \) is the *energy change due to internal stresses*, and \( \rho \mathbf{g} \cdot \mathbf{u} \) is the change of *potential energy* of gravity forces.
Complete Navier–Stokes equations

Mass conservation: \( \frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \)

Momentum conservation: \( \rho \frac{Du}{Dt} = \nabla \cdot \mathbf{\sigma} + \rho \mathbf{g}, \quad \text{(here: } \mathbf{\sigma} = \sigma^T). \)

Energy conservation: \( \frac{D}{Dt} \left( \rho e + \frac{1}{2} \rho \mathbf{u} \cdot \mathbf{u} \right) = -\nabla \cdot \mathbf{q} + \nabla \cdot (\mathbf{\sigma} \cdot \mathbf{u}) + \rho \mathbf{g} \cdot \mathbf{u} + h. \)

Equations of state and constitutive relations:

- Thermal equation of state: \( \rho = \rho(p, T). \)
  
  For a perfect gas: \( \rho = \frac{p}{RT}, \) where \( R \) is the \textit{universal gas constant}. 

Complete Navier–Stokes equations

Mass conservation: \( \frac{D \rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \)

Momentum conservation: \( \rho \frac{Du}{Dt} = \nabla \cdot \mathbf{\sigma} + \rho \mathbf{g} , \) (here: \( \mathbf{\sigma} = \mathbf{\sigma}^T \)).

Energy conservation: \( \frac{D}{Dt} \left( \rho \ e + \frac{1}{2} \rho \mathbf{u} \cdot \mathbf{u} \right) = -\nabla \cdot \mathbf{q} + \nabla \cdot (\mathbf{\sigma} \cdot \mathbf{u}) + \rho \mathbf{g} \cdot \mathbf{u} + h. \)

Equations of state and constitutive relations:

- **Thermal equation of state:** \( \rho = \rho(p, T). \)
- **Constitutive law for fluid:** \( \mathbf{\sigma} = \mathbf{\sigma}(\mathbf{u}, p) = \mathbf{\tau}(\mathbf{u}) - p \mathbf{I}. \)
  
  For *Newtonian fluids*: \( \mathbf{\tau} = \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T) - \frac{2}{3} \mu (\nabla \cdot \mathbf{u}) \mathbf{I}. \)

Other relations may be used, for example: \( \mathbf{\tau} = \mathbf{0} \) for an inviscid fluid, or some nonlinear relationships for non-Newtonian fluids.
Complete Navier–Stokes equations

Mass conservation: \( \frac{\partial \rho}{\partial t} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \)

Momentum conservation: \( \rho \frac{\partial \mathbf{u}}{\partial t} = \nabla \cdot \mathbf{\sigma} + \rho \mathbf{g}, \) (here: \( \sigma = \sigma^T \)).

Energy conservation: \( \frac{\partial}{\partial t} \left( \rho e + \frac{1}{2} \rho \mathbf{u} \cdot \mathbf{u} \right) = -\nabla \cdot \mathbf{q} + \nabla \cdot (\mathbf{\sigma} \cdot \mathbf{u}) + \rho \mathbf{g} \cdot \mathbf{u} + h. \)

Equations of state and constitutive relations:

- **Thermal equation of state**: \( \rho = \rho(p, T). \)
- **Constitutive law for fluid**: \( \mathbf{\sigma} = \mathbf{\sigma}(u, p) = \mathbf{\tau}(u) - p \mathbf{I}. \)
- **Thermodynamic relation** for state variables: \( e = e(p, T). \)

For a calorically perfect fluid: \( e = c_V T, \) where \( c_V \) is the *specific heat at constant volume*. This equation is sometimes called the *caloric equation of state*. 
Complete Navier–Stokes equations

Mass conservation: \( \frac{D\rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \)

Momentum conservation: \( \rho \frac{D\mathbf{u}}{Dt} = \nabla \cdot \mathbf{\sigma} + \rho \mathbf{g}, \) (here: \( \mathbf{\sigma} = \mathbf{\sigma}^T \)).

Energy conservation: \( \frac{D}{Dt} \left( \rho e + \frac{1}{2} \rho \mathbf{u} \cdot \mathbf{u} \right) = -\nabla \cdot \mathbf{q} + \nabla \cdot (\mathbf{\sigma} \cdot \mathbf{u}) + \rho \mathbf{g} \cdot \mathbf{u} + h. \)

Equations of state and constitutive relations:

- Thermal equation of state: \( \rho = \rho(p, T). \)
- Constitutive law for fluid: \( \mathbf{\sigma} = \mathbf{\sigma}(\mathbf{u}, p) = \mathbf{\tau}(\mathbf{u}) - p \mathbf{I}. \)
- Thermodynamic relation: \( e = e(p, T). \)
- Heat conduction law: \( \mathbf{q} = \mathbf{q}(\mathbf{u}, T). \)

*Fourier’s law* of thermal conduction with convection: \( \mathbf{q} = -k \nabla T + \rho c \mathbf{u} T, \) where \( k \) is the *thermal conductivity* and \( c \) is the *thermal capacity* (the *specific heat*).
Complete Navier–Stokes equations

Mass conservation: \[ \frac{D \rho}{Dt} + \rho \nabla \cdot \mathbf{u} = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0. \]

Momentum conservation: \[ \rho \frac{Du}{Dt} = \nabla \cdot \mathbf{\sigma} + \rho \mathbf{g}, \quad \text{(here: } \mathbf{\sigma} = \mathbf{\sigma}^T). \]

Energy conservation: \[ \frac{D}{Dt} \left( \rho e + \frac{1}{2} \rho \mathbf{u} \cdot \mathbf{u} \right) = -\nabla \cdot \mathbf{q} + \nabla \cdot (\mathbf{\sigma} \cdot \mathbf{u}) + \rho \mathbf{g} \cdot \mathbf{u} + h. \]

Equations of state and constitutive relations:

- Thermal equation of state: \( \rho = \rho(p, T). \)
- Constitutive law for fluid: \( \mathbf{\sigma} = \mathbf{\sigma}(u, p) = \mathbf{\tau}(u) - p \mathbf{I}. \)
- Thermodynamic relation: \( e = e(p, T). \)
- Heat conduction law: \( q = q(u, T). \)

Remarks:

- There are 5 conservation equations for 14 unknown fields: \( \rho, u, \mathbf{\sigma}, e, q. \)
Complete Navier–Stokes equations

Mass conservation: \( \frac{D \rho}{Dt} + \rho \nabla \cdot u = \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho u) = 0. \)

Momentum conservation: \( \rho \frac{Du}{Dt} = \nabla \cdot \sigma + \rho g, \) \( \) (here: \( \sigma = \sigma^T \)).

Energy conservation: \( \frac{D}{Dt} \left( \rho e + \frac{1}{2} \rho u \cdot u \right) = -\nabla \cdot q + \nabla \cdot (\sigma \cdot u) + \rho g \cdot u + h. \)

Equations of state and constitutive relations:

- **Thermal equation of state:** \( \rho = \rho(p, T). \)

   - Boundary layers
Reynolds number

Definition (Reynolds number)

The **Reynolds number** is a dimensionless parameter defined as

$$Re = \frac{U L}{\nu}$$

where:
- $U$ denotes a typical **flow speed**,
- $L$ is a characteristic **length scale** of the flow,
- $\nu$ is the **kinematic viscosity** of the fluid.
Reynolds number

Definition (Reynolds number)

The Reynolds number is a dimensionless parameter defined as

\[
Re = \frac{UL}{\nu}
\]

where: \(U\) denotes a typical flow speed,

\(L\) is a characteristic length scale of the flow,

\(\nu\) is the kinematic viscosity of the fluid.

The Reynolds number gives a rough indication of the relative amplitudes of two key terms in the equations of motion, namely,

1. the inertial term: \(|(u \cdot \nabla)u|\),
2. the viscous term: \(|\nu \triangle u|\).
Reynolds number

Definition (Reynolds number)

The Reynolds number is a dimensionless parameter defined as

\[ Re = \frac{UL}{\nu} \]

where: 
- \( U \) denotes a typical flow speed,
- \( L \) is a characteristic length scale of the flow,
- \( \nu \) is the kinematic viscosity of the fluid.

The Reynolds number gives a rough indication of the relative amplitudes of two key terms in the equations of motion, namely,

1. the inertial term: \( |(u \cdot \nabla)u| = O(U^2/L) \),
2. the viscous term: \( |\nu \triangle u| \).

- Derivatives of the velocity components, such as \( \frac{\partial u}{\partial x} \), will typically be of order \( U/L \), that is, the components of \( u \) change by amounts of order \( U \) over distances of order \( L \).
Reynolds number

**Definition (Reynolds number)**

The **Reynolds number** is a dimensionless parameter defined as

\[
Re = \frac{UL}{\nu}
\]

where:  
- \(U\) denotes a typical **flow speed**,  
- \(L\) is a characteristic **length scale** of the flow,  
- \(\nu\) is the **kinematic viscosity** of the fluid.

The Reynolds number gives a rough indication of the **relative amplitudes of two key terms** in the equations of motion, namely,

1. the **inertial term**: \(|(u \cdot \nabla)u| = O(U^2/L)\),
2. the **viscous term**: \(|\nu \Delta u| = O(\nu U/L^2)\).

- Typically, these derivatives of velocity will themselves change by amounts of order \(U/L\) over distances of order \(L\) so the second derivatives, such as \(\frac{\partial^2 u}{\partial x^2}\), will be of order \(U/L^2\).
Reynolds number

Definition (**Reynolds number**)  
The **Reynolds number** is a dimensionless parameter defined as  
\[ Re = \frac{U L}{\nu} \]
where:  
- \( U \) denotes a typical **flow speed**,  
- \( L \) is a characteristic **length scale** of the flow,  
- \( \nu \) is the **kinematic viscosity** of the fluid.

The Reynolds number gives a rough indication of the relative amplitudes of two key terms in the equations of motion, namely,

1. **the inertial term**: \(|(u \cdot \nabla)u| = O(U^2/L)|
2. **the viscous term**: \(|\nu \triangle u| = O(\nu U/L^2)|

\[
\frac{|\text{inertial term}|}{|\text{viscous term}|} = O\left(\frac{U^2/L}{\nu U/L^2}\right) = O(Re) .
\]
Reynolds number

Definition (Reynolds number)

\[ Re = \frac{UL}{\nu} \]

There are two extreme cases of viscous flow:

1. **High Reynolds number flow** – for \( Re \gg 1 \): a flow of a fluid of small viscosity, where **viscous effects** can be on the whole **negligible**.

2. **Low Reynolds number flow** – for \( Re \ll 1 \): a **very viscous** flow.
### Reynolds number

**Definition (Reynolds number)**

\[ Re = \frac{UL}{\nu} \]

There are two extreme cases of viscous flow:

1. **High Reynolds number flow** – for \( Re \gg 1 \): a flow of a fluid of **small viscosity**, where **viscous effects** can be on the whole **negligible**.
   - Even then, however, viscous effects become important in **thin boundary layers**, where the unusually large velocity gradients make the viscous term much larger than the estimate \( \nu U/L^2 \). The larger the Reynolds number, the thinner the boundary layer: \( \delta/L = O(1/\sqrt{Re}) \) (\( \delta \) – typical thickness of boundary layer).
   - A large Reynolds number is **necessary** for **inviscid theory** to apply over most of the flow field, but it is not **sufficient**.
   - At high Reynolds number (\( Re \sim 2000 \)) steady flows are often **unstable** to small disturbances, and may, as a result become **turbulent** (in fact, \( Re \) was first employed in this context).

2. **Low Reynolds number flow** – for \( Re \ll 1 \): a **very viscous flow**.
There are two extreme cases of viscous flow:

1. **High Reynolds number flow** – for $Re \gg 1$: a flow of a fluid of small viscosity, where viscous effects can be on the whole negligible.

2. **Low Reynolds number flow** – for $Re \ll 1$: a very viscous flow.
   - There is no turbulence and the flow is extremely ordered and nearly reversible ($Re \sim 10^{-2}$).

4 Features of viscous flow
   - Viscous diffusion of vorticity
   - Convection and diffusion of vorticity
   - Boundary layers
Plane parallel shear flow

$u = u(y, t) = [u(y, t), 0, 0]$

Such flow automatically satisfies the incompressibility condition: $\nabla \cdot u = 0$, and in the absence of gravity the incompressible Navier–Stokes equations of motion reduce to:

$$\frac{\partial u}{\partial t} = -\frac{1}{\rho_0} \frac{\partial p}{\partial x} + \nu \frac{\partial^2 u}{\partial y^2}, \quad \frac{\partial p}{\partial y} = \frac{\partial p}{\partial z} = 0.$$

(The gravity can be ignored if it simply modifies the pressure distribution in the fluid and does nothing to change the velocity.)
Plane parallel shear flow

\[ u = u(y, t) = [u(y, t), 0, 0] \]

Such flow automatically satisfies the incompressibility condition: \( \nabla \cdot u = 0 \), and in the absence of gravity the incompressible Navier–Stokes equations of motion reduce to:

\[
\frac{\partial u}{\partial t} = -\frac{1}{\rho_0} \frac{\partial p}{\partial x} + \nu \frac{\partial^2 u}{\partial y^2}, \quad \frac{\partial p}{\partial y} = \frac{\partial p}{\partial z} = 0.
\]

- The first equation implies that \( \frac{\partial p}{\partial x} \) cannot depend on \( x \), while the remaining two equations imply that \( p = p(x, t) \); therefore, \( \frac{\partial p}{\partial x} \) may only depend on \( t \).
- There are important circumstances when the flow is *not* being driven by any externally applied pressure gradient, which permits to assert that the pressures at \( x = \pm \infty \) are equal. All this means that \( \frac{\partial p}{\partial x} = 0 \).
Newtonian fluids Navier–Stokes equations Reynolds number Features of viscous flow

Plane parallel shear flow

\[ u = u(y, t) = [u(y, t), 0, 0] \]

Such flow automatically satisfies the incompressibility condition: \( \nabla \cdot u = 0 \), and in the absence of gravity the incompressible Navier–Stokes equations of motion reduce to:

\[
\frac{\partial u}{\partial t} = -\frac{1}{\rho_0} \frac{\partial p}{\partial x} + \nu \frac{\partial^2 u}{\partial y^2}, \quad \frac{\partial p}{\partial y} = \frac{\partial p}{\partial z} = 0.
\]

Diffusion equation for viscous incompressible flow

For a gravity-independent plane parallel shear flow, not driven by any externally applied pressure gradient, the velocity \( u(y, t) \) must satisfy the one-dimensional diffusion equation:

\[
\frac{\partial u}{\partial t} = \nu \frac{\partial^2 u}{\partial y^2}.
\]
Example (The flow due to impulsively moved plane boundary)

- Viscous fluid lies at rest in the region:
  \[(\text{Problem A}) \quad 0 < y < \infty, \quad (\text{Problem B}) \quad 0 < y < h.\]

- At \( t = 0 \) the rigid boundary at \( y = 0 \) is suddenly jerked into motion in the \( x \)-direction with constant speed \( U \).

- By virtue of the no-slip condition the fluid elements in contact with the boundary will immediately move with velocity \( U \).
Viscous diffusion of vorticity

Example (The flow due to impulsively moved plane boundary)

- Viscous fluid lies at rest in the region:
  - (Problem A) $0 < y < \infty$
  - (Problem B) $0 < y < h$

- At $t = 0$ the rigid boundary at $y = 0$ is suddenly jerked into motion in the $x$-direction with constant speed $U$.

- By virtue of the no-slip condition the fluid elements in contact with the boundary will immediately move with velocity $U$.

Mathematical statement of the problem

The flow velocity $u(y, t)$ must satisfy the one-dimensional diffusion equation

$$\frac{\partial u}{\partial t} = \nu \frac{\partial^2 u}{\partial y^2},$$

together with the following conditions:

1. Initial condition:
   - $u(y, 0) = 0$ (for $y \geq 0$),

2. Boundary conditions:
   - (Problem A) $u(0, t) = U$ and $u(\infty, t) = 0$ (for $t \geq 0$),
   - (Problem B) $u(0, t) = U$ and $u(h, t) = 0$ (for $t \geq 0$).
Viscous diffusion of vorticity

Solution to Problem A:

\[ u = U \left[ 1 - \frac{1}{\sqrt{\pi}} \int_0^\eta \exp \left( -\frac{s^2}{4} \right) \, ds \right] \quad \text{with} \quad \eta = \frac{y}{\sqrt{\nu t}}, \quad \omega = - \frac{\partial u}{\partial y} = \frac{U}{\sqrt{\pi \nu t}} \exp \left( -\frac{y^2}{4\nu t} \right). \]

The flow is largely confined to a distance of order \( \sqrt{\nu t} \) from the moving boundary: the velocity and vorticity are very small beyond that region.

**Vorticity diffuses** a distance of order \( \sqrt{\nu t} \) in time \( t \). Equivalently, the time taken for vorticity to diffuse a distance \( h \) is of the order \( \frac{h^2}{\nu} \).
Viscous diffusion of vorticity

Solution to Problem B:

\[ u = U \left(1 - \frac{y}{h}\right) - \frac{2U}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \exp \left(-\frac{n^2 \pi^2 \nu t}{h^2}\right). \]

For times greater than \( \frac{h^2}{\nu} \) the flow has almost reached its steady state and the vorticity is almost distributed uniformly throughout the fluid.
**Convection and diffusion of vorticity**

**Vorticity equation for viscous flows**

In general:

\[
\nabla \times \frac{\partial \omega}{\partial t} + (\mathbf{u} \cdot \nabla) \omega = (\omega \cdot \nabla) \mathbf{u} + \nu \triangle \omega.
\]

For a two-dimensional flow (\( \omega \perp \mathbf{u} \)):

\[
\frac{\partial \omega}{\partial t} + (\mathbf{u} \cdot \nabla) \omega = \nu \left( \frac{\partial^2 \omega}{\partial x^2} + \frac{\partial^2 \omega}{\partial y^2} \right).
\]

Observation: In general, there is both convection and diffusion of vorticity in a viscous flow.
Convection and diffusion of vorticity

Vorticity equation for viscous flows

In general:

\[
\nabla \times \frac{\partial \omega}{\partial t} + (u \cdot \nabla) \omega = (\omega \cdot \nabla)u + \nu \Delta \omega.
\]

For a two-dimensional flow \((\omega \perp u)\):

\[
\frac{\partial \omega}{\partial t} + (u \cdot \nabla) \omega = \nu \left( \frac{\partial^2 \omega}{\partial x^2} + \frac{\partial^2 \omega}{\partial y^2} \right).
\]

Observation: In general, there is both convection and diffusion of vorticity in a viscous flow.
There is an inviscid ‘mainstream’ flow: $u = \alpha x, v = -\alpha y$ (here, $\alpha > 0$ is a constant), towards a stagnation boundary at $y = 0$.

This fails to satisfy the no-slip condition at the boundary, but the mainstream flow speed $\alpha |x|$ increases with distance $|x|$ along the boundary. By the Bernoulli’s theorem, the mainstream pressure decreases with distance along the boundary in the flow direction.

Thus, one may hope for a thin, unseparated boundary layer which adjusts the velocity to satisfy the no-slip condition.
Convection and diffusion of vorticity

Example (Plane flow towards a stagnation point)

- The boundary layer, in which all the vorticity in concentrated, has thickness of order $\sqrt{\nu/\alpha}$.
- In this boundary layer there is a steady state balance between the viscous diffusion of vorticity from the wall and the convection of vorticity towards the wall by the flow.
- If $\nu$ decreases the diffusive effect is weakened, while if $\alpha$ increases the convective effect is enhanced (in either case the boundary layer becomes thinner).
Boundary layers

- Steady flow past a fixed wing may seem to be wholly accounted for by inviscid theory. In particular, the fluid in contact with the wing appears to slip along the boundary.
- In fact, there is no such slip. Instead there is a very thin boundary layer where the inviscid theory fails and viscous effects are very important.
Steady flow past a fixed wing may seem to be wholly accounted for by inviscid theory. In particular, the fluid in contact with the wing appears to slip along the boundary. In fact, there is no such slip. Instead there is a very thin boundary layer where the inviscid theory fails and viscous effects are very important.

A boundary layer is a very thin layer along the boundary across which the flow velocity undergoes a smooth but rapid adjustment to precisely zero (i.e. no-slip) on the boundary itself.
In certain circumstances **boundary layers may separate** from the boundary, thus causing the whole flow of low-viscosity fluid to be quite different to that predicted by inviscid theory.
In certain circumstances boundary layers may separate from the boundary, thus causing the whole flow of low-viscosity fluid to be quite different to that predicted by inviscid theory.

The behaviour of a fluid of even very small viscosity may, on account of boundary layer separation, be completely different to that of a (hypothetical) fluid of no viscosity at all.
